**Abstract**—Compact, light, and low power consumption communications equipment is required for the small satellites. For such restriction of the resources in the spacecrafts, we propose a non-mechanical, compact optical terminal equipped with a two-dimensional laser array. A laser beam is transmitted by selecting the laser pixel corresponding to the direction of the optical signal received from the counter terminal. The beams are not deflected by a mechanical mirror. Instead, they are turned on and off one after the other in accordance with the direction from which optical signals are received. Multiple-input multiple-output operation is possible in this configuration. The non-mechanical transceiver can facilitate a reduction in the size of the optical communications system. This paper presents the basic concept of a non-mechanical compact transceiver with a two-dimensional laser array for optical wireless communications.

## I. INTRODUCTION

The advantages of optical communications as compared to radio frequency (RF) communications include a wider bandwidth, a larger capacity, lower power consumption, more compact equipment, greater security against eavesdropping, better protection against interference, and the absence of regulatory restrictions [1]. Moreover, the demand for high-data-rate transmission from spaceborne observation platforms is steadily increasing [2]. Free-space optical (FSO) communications systems are expected to play an important role in providing such high-data-rate communications, and optical technologies for satellite networks are expected to revolutionize space system architecture [3]. However, maintaining a line of sight between transceivers is particularly difficult because of the small divergence angle of the laser beams. Thus, minimizing the requirements for the tracking system and ensuring the steady operation of the onboard optical terminal are important for the realization of commercial applications.

Optical terminals tend to have a large mass because optical tracking systems need to have mechanically movable parts for coarse laser pointing and tracking. Reductions in the mass, power, and volume can decrease the interference to the other missions on the satellites.

Non-mechanical movable architecture is very attractive for the robust and lifelong operation of the optical terminal in orbit. The small satellite community still uses 9.6-kbps communication links by employing ham radio communications because of resource constraints in the nano-class satellites [4–6]. The compact terminal can be used in nano-class satellites that have a mass of the order of a few tens of kilograms. In addition, there is a significant advantage with regard to the frequency-licensing problems faced by satellites, and the optical frequency carrier will be very useful to the small satellite community.

In this paper, we propose the concept of a compact free-space laser communications terminal with a vertical-cavity surface-emitting laser (VCSEL) array. There are no mechanically moving parts in this optical system. This compact terminal can receive optical communications signals from multiple platforms and can transmit multiple optical communications beams to the counter terminals. Therefore, such an optical system can serve as a multiple-input multiple-output (MIMO) system. Section II covers the recent history of optical space communications. Section III describes the conceptual terminal design involving a charge-coupled device (CCD) and a laser array and presents the system analysis of the optical link budget.

## II. HISTORY OF OPTICAL SPACE COMMUNICATIONS

In Japan, the National Institute of Information and Communications Technology (NICT, formerly Communications Research Laboratory) performed the first bidirectional laser communication by using the laser communications equipment (LCE) on Engineering Test Satellite VI (ETS VI), which was launched in August 1994. The data rate of 1 Mbps was demonstrated [7]. In 1995, the Jet Propulsion Laboratory (JPL) and NICT conducted a ground-to-space optical communications demonstration called the Ground-to-Orbit Lasercom Demonstration (GOLD) [8].

The European Space Agency (ESA) conducted the Semiconductor Laser Intersatellite Link Experiment (SILEX) using laser communications terminals designed for 50-Mbps low earth orbit (LEO)-geostationary earth orbit (GEO) intersatellite link (ISL) applications. A

SILEX demonstration conducted in November 2001 that linked the System Probatoire/Satellite Pour d’Observation de la Terra 4 (SPOT-4) satellite to the Advanced Relay Technology Mission Satellite (ARTEMIS) marked the first transmission of an image at 50 Mbps over a laser link [9]. Ground-to-ARTEMIS optical communications experiments were successfully conducted in November 2001 [10] and in September 2003 [11].

The Optical Inter-orbit Communications Engineering Test Satellite (OICETS, or “Kirari” in Japanese) was launched in August 2005. In December 2005, the demonstration of the first bidirectional laser communication between OICETS and ARTEMIS was successfully conducted [12–15]. Following these intersatellite experiments, the Kirari optical communication demonstration experiments were conducted by using the NICT optical ground station (KODEN) in collaboration with the Japan Aerospace Exploration Agency (JAXA) in March, May, and September 2006. In March 2008, a 5.5-Gbps intersatellite optical communication link was successfully tested by using German laser terminals; this data rate is the fastest in space-borne communications to date [16].

On the other hand, there is the other direction aiming for small terminals with rather low data rates but it is useful for the small satellite community especially for the licensing issue. The proposed technique will expand the new utilization of the communications means in satellite communications.

Figure 1. Configuration of the proposed compact laser communications transceiver

### III. CONCEPTUAL TERMINAL DESIGN

#### A. System Configuration

Figure 1 shows the configuration of the proposed compact laser communications transceiver. The laser beam from the counter terminal passes through the telescope lens, is reflected from the beam splitter and is detected by the CCD sensor. The CCD sensor detects the direction of the line of sight of the counter terminal, and one of the array lasers is selected according to the direction of the signal received by the CCD. A CCD with a pixel size equal to that of the XGA (1280 × 1024) is used. The centroid of the pixels is calculated in the computer, and the laser beam corresponding to the direction of the centroid is turned on. Figure 2 shows the

photograph of the manufactured compact laser communications transceiver and the control computer system. With this configuration, multiple inputs from multiple platforms can possible with the parallel laser spot detection processing, and the MIMO configuration can be possible as well [17].

Figure 2. Photograph of the manufactured compact laser communications transceiver

#### B. Optical part of the transceiver

The laser beam is transmitted from the two-dimensional laser array through the beam splitter and the telescope lens. The laser beam is selected by the centroid calculation in the computer. The beam divergence angle of the selected laser beam covers the angular interval between adjacent laser arrays [18]. Two adjacent laser beams are turned on simultaneously to ensure that the laser transmission is not interrupted and to maintain a constant optical intensity at the counter terminal. Figure 3 shows the beam transmission configuration for a two-dimensional laser array. With this transmission method, the transmitted laser beam is not interrupted during the tracking of the counter terminal. Each laser beam is combined by an interval at the half width at half maximum (HWHM). Therefore, if the two adjacent laser beams are turned on simultaneously, the optical intensity can be almost constant at the counter terminal.

For the transmitter, we use an 8 × 8 VCSEL array, as shown in Fig. 4, for the first evaluation model. We choose a VCSEL because it is easy to arrange it in an array, there is no mechanical part, and it is readily available [19,20]. The maximum output power of one pixel is 4 mW at a wavelength of 850 nm as shown in TABLE I. The laser diode can be modulated at above 2.5 GHz. An example of the beam pattern is measured by a beam profiler at 30 cm distance from the compact laser communications transceiver as shown in Fig. 5. All the VCSELs could be turned on individually. The beam pattern from the VCSEL used here exhibits a donuts mode instead of the Gaussian one. The beam divergence for this evaluation model was designed to be 2 degrees for one VCSEL, which is more broadened beam divergence than that of the real system because the number of the VCSEL array is not enough. As shown in the next subsection, a large number of pixels are required depending on the angular coverage of the transmitter.

Figure 6 shows the optical part of the manufactured compact laser communications transceiver. The small telescope consists of 9 lenses. The VCSEL is mounted at the end of the small telescope and the CCD sensor is mounted on the upper side of the telescope as shown in Fig. 6. The size of the optical part of the telescope (lens mount) is  $13.5 \times 6 \times 11$  cm, and the mass is 1 kg as shown in TABLE II.

Figure 6. Optical part of the compact laser communication transceiver

Figure 7. Electrical part of the compact laser communication transceiver

C. Electrical part of the transceiver

Laser beams in the VCSEL array are modulated according to the received laser spot extracted by the control computer system as shown in Fig. 1. Two 32-channel digital I/O boards are installed and can transmit the data at a data rate of 25 Mbps. Figure 7 shows the photograph of the electrical part of the manufactured laser driver. The electrical part as shown in Fig. 7 can drive 64 channels of the VCSEL by the selected signal from the digital I/O boards. The laser diode is driven at an average power of 2 mW by the driver electronics. The electrical part of the compact laser communications transceiver has the mass of 3.1 kg, the size of  $27 \times 26 \times 10$  cm, and the power consumption of less than 10 W as shown in TABLE II.

	dBm	-72.7	-62.9
Link margin	dB	2.2	3.6

D. System Analysis

TABLE III summarizes the results of the link budget analysis for the proposed compact optical transceiver. The optical link is designed to connect an optical ground station to a LEO satellite. The output laser power for a pixel of the VCSEL array is assumed to be 2 mW at 850 nm wavelength. The beam divergence angle is set at 869  $\mu$ rad for a single laser pixel for the full width at 1/e<sup>2</sup> maximum (FWe<sup>2</sup>M), and the angular coverage of the transmitter is 60° for a  $1024 \times 1024$  array, which is enough to cover the attitude error of the satellites. The overlap of the beams is set to occur at the HWHM. The beam pointing error can be considered as zero because the transmitting power can be doubled by turning on the adjacent two VCSELs simultaneously. The beam diameter of the transmitter is 1.25 mm. The link distance is assumed to be 1000 km from the optical ground station to the LEO satellite. If we use a receiving telescope with a 1.5-m diameter, the link margin will be 3.6 dB at a data rate of 1 Mbps. The data rate is rather lower as compared with that of a trunk optical communications line; however, some nano-class satellites still use a data rate of the order of 1.2 k to 9.6 kbps [4–6]. Despite the low data rate, this system is advantageous because it overcomes the frequency-licensing problem of the satellites. The compact optical transceiver can be used in such the nano-class satellite community for space communications in the future.

TABLE IV tabulates the results of the link budget analysis for a horizontal terrestrial optical communication link on the ground. By using the proposed non-mechanical compact transceiver, a data rate of 1 Gbps can be realized for a distance up to 1 km with an angular coverage of 60°. The diameter of the receiver aperture is 5 cm in this case. If a receiver aperture with a diameter of 3 cm is used, a data rate of 1 Gbps can be realized for a distance up to 700 m. As shown in Table IV, the proposed non-mechanical method can be applied to terrestrial free-space laser communications. If the proposed terminal can be made very compact, mobile users can use the high-data-rate optical link without the mechanical tracking system on the ground, like a digital camera. Setting up the optical transceivers is easy and their installation is not complicated. In the future, the applicable fields for the optical transceivers will include not only satellite communications but also high-speed cell phone communications, wireless LAN, mobile communications, and building-to-building fixed high data rate communications without any difficulties.

IV. CONCLUSION

A non-mechanical and very compact optical transceiver has been presented. A VCSEL array is used in the transceiver, and the laser pixel that is turned on depends on the direction of the counter terminal from which the CCD receives a signal. The mass, volume, and power of the proposed system can be reduced because it contains no mechanically movable structures. In this study, an  $8 \times 8$  VCSEL has been used. The angular coverage of the optical terminal can be extended if a larger number of pixels are used. As there are no regulatory restrictions on the use of the optical frequency, the proposed compact laser communications transceiver will be useful for downloading data from nano-class satellites in future applications.

**Morio Toyoshima** received the B.S. and M.S. degrees in electronic engineering from Shizuoka University, Shizuoka, Japan, in 1992 and in 1994, and the Ph.D. degree from the University of Tokyo, Tokyo, Japan, in 2003 in electronics engineering, respectively. He joined the Communications Research Laboratory, Ministry of Posts and Telecommunications in 1994 (at present, National Institute of Information and Communications Technology, NICT) and soon after was engaged in research for the Engineering Test Satellite VI (ETS-VI) optical communication experiment and later involved in the Ground-to-Orbit Laser-com Demonstration

(GOLD) experiment with Jet Propulsion Laboratory. He joined the Japan Aerospace Exploration Agency (JAXA) (former NASDA), for the development of the Optical Inter-orbit Communications Engineering Test Satellite (OICETS) from 1999 to 2003. In December 2003, he became a Senior Researcher of the Optical Space Communications Group, (NICT, former CRL), Japan. Starting in October 2004, he spent one year as a guest scientist at Vienna University of Technology, Austria, in the field of optical space communications. Since April 2006 he works in the New Generation Wireless Communications Research Center, NICT, and he conducted the Kirari Optical Communication Demonstration Experiments (KODEN) which is the laser communication experiments between the NICT optical ground station and OICETS. His research interests are laser beam propagation through atmospheric turbulence, space laser communications and quantum cryptography. Dr. Toyoshima is a member of the Institute of Electrical and Electronic Engineers, the Optical Society of America, the Institute of Electronics, Information and Communication Engineers, and the Japan Society for Aeronautical and Space Science.

**Naoki Miyashita** received Ph.D. in aerospace engineering from Tokyo Institute of Technology, Tokyo, Japan in 2006. He joined the National Institute of Information Communications Technology, Tokyo, Japan from 2006.

**Yoshihisa Takayama** earned Ph. D. in electronics and information engineering from Hokkaido University, Sapporo, Hokkaido, Japan in 1998. He joined the National Institute of Information Communications Technology (NICT), former Communications Research Laboratory, Tokyo, Japan in 1999. He had joined Japan Aerospace Exploration Agency for OICETS project from 2004 to 2006 and returned to NICT in 2007. His current research interests are phase conjugate optics, photonic crystals, computational electromagnetics, and free space laser communications.

**Hiroo Kunimori** was born in Hiroshima, Japan. He Received the B.S. degree in information science from Kyoto University, Kyoto, Japan, in 1978. He joined the Radio Research Laboratory (at present, National Institute of Information and Communications Technology), Tokyo, Japan, in 1981, where he has been engaged in geodetic Very Long Baseline Interferometer, Space and Time Measurement, and Satellite Laser Ranging system. Since 1995, he has been developed a multi point Satellite Laser Ranging systems in Metropolitan Tokyo and applied for space optical communications. Since 2004, he has worked as a sub-Leader for the next generation of Laser Communication Satellite Technology Research Project (NeLS), at present, a Chief at Project Office of Satellite Laser Communications of Space Communications Group. Mr. Kunimori is a member of the Institute of Electronics, Information and Communication Engineers (IEICE), the Geodetic Society of Japan(GSJ), the Japan Society of Aeronautical and Space Sciences,(JSASS) and the American Geophysical Union(AGU).

**Shinichi Kimura** received the B. S. degree in chemistry on drug manufacturing from Tokyo University, Tokyo, Japan, in 1988 and M. S. and Ph. D. degrees in pharmacology from Tokyo University, Tokyo, Japan, in 1990 and 1993 respectively.

In 1993 he joined the Communications Research Laboratory (which was converted to the National Institute of Information and Communication Technology in 2004) and held an additional post of a guest associate professor of The University of Elecreeo-Communications. He moved to Tokyo University

of Science 2007 and he is an associate professor of Department of Electrical Engineering, Faculty of Science & Technology.

He has been engaged in the space robotics, system engineering, and autonomous control technologies. He made experiments on Manipulator Flight Demonstration on STS-87, Engineering Test Satellite VII which is the first tele-robotic satellite, visual analysis experiment of deployable antenna (LDREX) and Micro-LabSat.

He is a member of "The Society of Instrument and Control Engineers", "The Japan Society for Aeronautical and Space Sciences", and "The Institute of Electrical and Electronics Engineers".
